 - Overview
 - Challenges
 - Future directions

Methods

Methods

A method is a function associated with a specific object (and, by extension, with the type of that object)

Methods

A method is a function associated with a specific object (and, by extension, with the type of that object)

A method corresponds to a data-type operation

Methods

A method is a function associated with a specific object (and, by extension, with the type of that object)

A method corresponds to a data-type operation

We call (or invoke) a method using a variable name, followed by the dot operator (`.`), followed by the method name, followed by its arguments separated by commas and enclosed in parentheses

Methods

A method is a function associated with a specific object (and, by extension, with the type of that object)

A method corresponds to a data-type operation

We call (or invoke) a method using a variable name, followed by the dot operator (`.`), followed by the method name, followed by its arguments separated by commas and enclosed in parentheses

```
>_ ~/workspace/ipp/programs
```

```
>>> import stdio
>>> x, y, z = 200, 300, 600
>>> xbits, ybits, zbits = x.bit_length(), y.bit_length(), z.bit_length()
>>> stdio.writeln(xbits)
8
>>> stdio.writeln(ybits)
9
>>> stdio.writeln(zbits)
10
```

Basic Data Types

Basic Data Types

Methods in the built-in `int` data type

```
>_ ~/workspace/ipp/programs
```

```
>>> dir(int)
['bit_length', 'conjugate']
```

Basic Data Types

Methods in the built-in `int` data type

```
>_ ~/workspace/ipp/programs  
  
>>> dir(int)  
['bit_length', 'conjugate']
```

Methods in the built-in `float` data type

```
>_ ~/workspace/ipp/programs  
  
>>> dir(float)  
['as_integer_ratio', 'conjugate', 'fromhex', 'hex', 'is_integer']
```

Basic Data Types

Methods in the built-in `int` data type

```
>_ ~/workspace/ipp/programs  
  
>>> dir(int)  
['bit_length', 'conjugate']
```

Methods in the built-in `float` data type

```
>_ ~/workspace/ipp/programs  
  
>>> dir(float)  
['as_integer_ratio', 'conjugate', 'fromhex', 'hex', 'is_integer']
```

Methods in the built-in `bool` data type

```
>_ ~/workspace/ipp/programs  
  
>>> dir(bool)  
['bit_length', 'conjugate']
```

Basic Data Types

Methods in the built-in `int` data type

```
>_ ~/workspace/ipp/programs  
  
>>> dir(int)  
['bit_length', 'conjugate']
```

Methods in the built-in `float` data type

```
>_ ~/workspace/ipp/programs  
  
>>> dir(float)  
['as_integer_ratio', 'conjugate', 'fromhex', 'hex', 'is_integer']
```

Methods in the built-in `bool` data type

```
>_ ~/workspace/ipp/programs  
  
>>> dir(bool)  
['bit_length', 'conjugate']
```

Methods in the built-in `str` data type

```
>_ ~/workspace/ipp/programs  
  
>>> dir(str)  
['capitalize', 'center', 'count', 'decode', 'encode', 'endswith', 'expandtabs', 'find', 'format',  
'index', 'isalnum', 'isalpha', 'isdigit', 'islower', 'isspace', 'istitle', 'isupper', 'join',

```

User-Defined Data Types

User-Defined Data Types

Color

<code>Color(r, g, b)</code>	constructs a new color <i>c</i> with red, green, and blue components <i>r</i> , <i>g</i> , and <i>b</i> , all integers between 0 and 255
<code>c.getRed()</code>	returns the red component of <i>c</i>
<code>c.getGreen()</code>	returns the green component of <i>c</i>
<code>c.getBlue()</code>	returns the blue component of <i>c</i>
<code>str(c)</code>	returns a string representation of <i>c</i>

User-Defined Data Types

Color	
<code>Color(r, g, b)</code>	constructs a new color <i>c</i> with red, green, and blue components <i>r</i> , <i>g</i> , and <i>b</i> , all integers between 0 and 255
<code>c.getRed()</code>	returns the red component of <i>c</i>
<code>c.getGreen()</code>	returns the green component of <i>c</i>
<code>c.getBlue()</code>	returns the blue component of <i>c</i>
<code>str(c)</code>	returns a string representation of <i>c</i>

To create an object of a user-defined data type, we call its constructor, using the name of the data type, followed by the constructor's arguments

User-Defined Data Types

Color	
<code>Color(r, g, b)</code>	constructs a new color <i>c</i> with red, green, and blue components <i>r</i> , <i>g</i> , and <i>b</i> , all integers between 0 and 255
<code>c.getRed()</code>	returns the red component of <i>c</i>
<code>c.getGreen()</code>	returns the green component of <i>c</i>
<code>c.getBlue()</code>	returns the blue component of <i>c</i>
<code>str(c)</code>	returns a string representation of <i>c</i>

To create an object of a user-defined data type, we call its constructor, using the name of the data type, followed by the constructor's arguments

We use a variable name to identify the object to be associated with the method we intend to call

User-Defined Data Types

Color	
<code>Color(r, g, b)</code>	constructs a new color <i>c</i> with red, green, and blue components <i>r</i> , <i>g</i> , and <i>b</i> , all integers between 0 and 255
<code>c.getRed()</code>	returns the red component of <i>c</i>
<code>c.getGreen()</code>	returns the green component of <i>c</i>
<code>c.getBlue()</code>	returns the blue component of <i>c</i>
<code>str(c)</code>	returns a string representation of <i>c</i>

To create an object of a user-defined data type, we call its constructor, using the name of the data type, followed by the constructor's arguments

We use a variable name to identify the object to be associated with the method we intend to call

In any data-type implementation, it is worthwhile to include an operation that converts an object's value to a string

User-Defined Data Types

Color	
<code>Color(r, g, b)</code>	constructs a new color <code>c</code> with red, green, and blue components <code>r</code> , <code>g</code> , and <code>b</code> , all integers between 0 and 255
<code>c.getRed()</code>	returns the red component of <code>c</code>
<code>c.getGreen()</code>	returns the green component of <code>c</code>
<code>c.getBlue()</code>	returns the blue component of <code>c</code>
<code>str(c)</code>	returns a string representation of <code>c</code>

To create an object of a user-defined data type, we call its constructor, using the name of the data type, followed by the constructor's arguments

We use a variable name to identify the object to be associated with the method we intend to call

In any data-type implementation, it is worthwhile to include an operation that converts an object's value to a string

We use the following form of the `import` statement to import a data type `XYZ` defined in a file `xyz.py`

```
1 from xyz import XYZ
```

User-Defined Data Types

User-Defined Data Types

InStream

<code>InStream(filename)</code>	a new input stream <i>in</i> , initialized from <i>filename</i> (defaults to standard input)
<code>in.isEmpty()</code>	is <i>in</i> empty?
<code>in.readInt()</code>	read a token from <i>in</i> , and return it as an integer
<code>in.readString()</code>	read a token from <i>in</i> , and return it as a string

User-Defined Data Types

InStream

<code>InStream(filename)</code>	a new input stream <i>in</i> , initialized from <i>filename</i> (defaults to standard input)
<code>in.isEmpty()</code>	is <i>in</i> empty?
<code>in.readInt()</code>	read a token from <i>in</i> , and return it as an integer
<code>in.readString()</code>	read a token from <i>in</i> , and return it as a string

OutStream

<code>OutStream(filename)</code>	a new output stream <i>out</i> that will write to <i>filename</i> (defaults to standard output)
<code>out.write(x)</code>	write <i>x</i> to <i>out</i>
<code>out.writeln(x)</code>	write <i>x</i> to <i>out</i> , followed by a newline
<code>out.writef(fmt, arg1, ...)</code>	write the arguments <i>arg</i> ₁ , ... to <i>out</i> as specified by the format string <i>fmt</i>
